EXPERIMENT 10

# Performance Optimization

**Project:** Hotel Booking using Low-Code in Zoho Creator

## AIM

To improve the responsiveness of the Hotel Booking application by simplifying forms, reports, and workflow processing.

## REQUIREMENTS

- Hotel Booking app with sample data
- Rooms, Bookings, and reports
- A repeatable set of test records

## DESIGN / MODULES

| Area | Optimization |
|---|---|
| Forms | Use clear required fields and avoid unnecessary calculations |
| Reports | Apply useful filters and show only necessary columns |
| Workflows | Avoid duplicate triggers and repeated lookups |
| Data model | Use appropriate field types and relationships |

## PROCEDURE

1. Record the current behaviour of the booking form and reports with the same sample data.
2. Remove unused fields and unnecessary subforms or repeated calculations where safe.
3. Filter reports by relevant date/status and reduce unnecessary displayed columns.
4. Review workflows for repeated queries, duplicate email actions, and unnecessary loops.
5. Validate date and room availability before creating a confirmed booking.
6. Repeat the same tests and compare observations. Do not claim performance improvements without measurements from the actual app.

## SAMPLE LOGIC / OUTPUT

Measure: form response observation, report load observation, workflow completion status, and number of unnecessary repeated lookups. Record results before and after using the same data.

## TEST CASES

| Test | Expected outcome |
|---|---|
| Open filtered booking report | Only relevant rows are displayed |
| Submit valid booking | Workflow completes without duplicate actions |
| Submit invalid date range | Validation prevents an invalid booking |

## RESULT

Optimization opportunities and a repeatable test procedure are documented. Actual speed improvements depend on the live application and data volume.
